- > The fix that costs nothing

Your demo's numbers are probably fake

In One Line: Run your demo twice with the same input. If the numbers move, they are noise — not results.

The ten-second test

Enter identical inputs. Run. Note the headline number. Run again.

Different answer? Nothing measured anything. Something called a random number and dressed it as a result.

Identical input, two runs, two different answers. This is not a result — it is a dice roll.

I failed my own test

My app showed a confident **+6.2% improvement**.

I ran it twice. **+1.84x**, then **+0.55x**. Same campaign. Same budget. The "improvement" was `random.uniform()` wobbling around a hardcoded table.

Worse: the learning loop was scored against that noise. It was optimising against a dice roll and reporting the wins.

The fix is not "delete the randomness"

Variance is realistic — a model that returns one flat number for one input looks fake in the other direction.

The fix is to **seed it from the input**:

```
seed = hash(campaign type + product + budget + audience)
```

Same campaign, same seed, same numbers — every time. A real change to the input is now the only thing that can move the result.

Why this matters more than your UI

A judge or an interviewer will ask where a number came from. "It varies" is not an answer you can recover from.

Next video: the funnel step almost everyone skips — and the impossible economics it hides.
