

A neuron does **three things**. That is all.

ONE NEURON DECIDES: LEND OR NOT?

a small loan application

multiply each input by its weight → add them up → cross the line or not

Learning is only this: nudging those weights until the answers come out right

- 1 Multiply each input by a **weight** — how much that input matters.
- 2 Add the results into one number. Income 0.9, credit 0.7, loans 0.4 → **0.61**.
- 3 Over the threshold? It **fires**. Loan approved.

REMEMBER THIS

Learning is only this: nudging weights until the answers come out right.
