

A signal is a value that tells you it changed

SIGNAL

The value notifies its watchers

The old way: you tell the view to update. The **signal** way: it already knows.

- 1 A signal holds a value and a **list of who is watching it**.
- 2 Change the value and every watcher is notified automatically.
- 3 No manual change detection, no wondering why the screen is stale.

REMEMBER

This is the same idea as a spreadsheet cell. Change one, the rest recalculate.
